The Leopard in the Arabian Peninsula – Distribution and Subspecies Status

James A. Spalton\(^1\) and Hadi M. Al Hikmani\(^1\)

\(^1\)Office of the Adviser for Conservation of the Environment, Diwan of Royal Court, PO Box 246, Muscat 113, Sultanate of Oman <acendrc@omantel.net.om>

Historically it was considered that there were four subspecies of leopards in the Arabian region. Today *P. p. jarvisi* no longer occurs and the ranges of *P. p. tulliana* and *P. p. saxicolor* have severely contracted north. Only *P. p. nimr*, the Arabian leopard, remains. Morphological data suggests nimr to be the smallest of the leopards and a distinct subspecies but this has yet to be conclusively confirmed by genetic evidence. Recent records give a bleak picture of the status of *P. p. nimr*. A few individuals survive in the Judean Desert and Negev Highlands while in the Arabian Peninsula leopards are known from just one location in the Republic of Yemen and one in the Sultanate of Oman. In Yemen the leopards of the Al Wada’a area are under great pressure from killing and from capture for trade. In Oman the situation is much more hopeful and the leopards of the Dhofar Mountains have benefited from comprehensive conservation measures. While the possibility, however remote, of the existence of other relict populations cannot be ruled out the need for urgent conservation action across the region is obvious given the reality that the Arabian leopard may soon be reduced to two, or even just one population in the wild.

**Introduction**

The leopard *Panthera pardus* once occurred throughout much of Arabia (Harrison & Bates 1991). However, over the past 100 years it has become increasingly threatened as a result of the depletion of its prey base, killing by hunters and shepherds and vulnerability of ever decreasing population size. The leopard is globally red listed as Least Concern, but *P. p. nimr* is classified as Critically Endangered (IUCN 2004) and is listed on Appendix I of the Convention on International Trade in Endangered Species (CITES).

Hemprich & Ehrenberg (1833) first described *Felis nimr*, based on an Abyssinian skin and partly on an Arabian one. By the middle of the 20th century it was generally considered that there was evidence for four subspecies in Arabia; *P. p. jarvisi* in Sinai to the west, *P. p. saxicolor* in Iraq to the north, *P. p. tulliana* from Syria south to the Dead Sea in the Levant with *P. p. nimr* extending over most of the region from the Jordan valley south and east to Oman and Yemen (Harrison 1968). In this paper we use published work and some new data to shed light on the historical distribution and current occurrence of *Panthera pardus* in the region and attempt to clarify the “subspecies” issue.

**Distribution**

*Panthera pardus jarvisi*

Pocock (in Harrison 1968) in 1932 described *P. p. jarvisi* from Sinai although the exact locality and origin of the specimen is not known. Harrison (1968) considered that the range of *P. p. jarvisi* extended south through the Hejaz of Saudi Arabia but later Harrison & Bates...
(1991) described *P. p. jarvisi* as occurring only in Sinai and ‘is probably little more than the local variant of nimr’.

Osborn & Helmy (1980) report a single specimen examined from Sinai but of unknown locality and list numerous published records and reports for the peninsula from 1872 to the early 1950s. Substantiated reports from recent years are lacking. In 1995, Saleh *et al.* (1995) who surveyed Ras Mohammed, Nabaq and Abu Gallum protected areas, reported tracks in Wadi El Omiyed and also reported that in May 1995 an adult leopard was caught in a leg-hold trap near the western boundary of Abu Gallum. In 1997 Prof. Ibrahim Helmy sighted a leopard near Abu Durba. In December 1997 there was a report of a leopard being sighted in Wadi Eltala and later the same month in Wadi Elgars, being a branch of Wadi Eltala (Ibrahim 1998). A camera-trapping programme and survey started in 1999 (Spalton 1999) has found no evidence of leopards in St. Katherine Protectorate or elsewhere in Sinai (Hussam El Alqamy, personal communication February 2006).

Nowell & Jackson (1996) recorded *P. p. jarvisi* as being in Sinai and extending east to the Judean desert. However, Ilani (1990) who radio-tracked leopards in the late 1970s and early 1980s reported that the leopards of the Judean desert and Negev Highlands were neither *P. p. jarvisi* or *P. p. tulliana* but resembled closest *P. p. nimr*. Shoemaker (1997) states that surveys conducted in December 1992 produced a maximum estimate of 8-10 leopards. Recent estimates based on molecular scatology are of a minimum of a male and two females in the Judean Desert and four males and one female in the Negev Highlands (Perez et al. 2006).

**Panthera pardus tulliana**

There are numerous reports of this subspecies in Syria, Palestine and Jordan in the late 19th and early 20th centuries (Harrison 1968). In Jordan records come from north of Aqaba, south of Petra and Wadi Zarqa Ma’en (Hardy 1947) and the most recent report was in 1987 (Qumsiyeh et al. 1993). In Nowell & Jackson (1996) *P. p. tulliana* is considered as the Anatolian leopard and only occurring in western Turkey. Harrison (1968) reports this subspecies in the Galilee area close to Lebanon where it is believed that the last specimen, an old male, was killed in 1965 (Mendelssohn 1990). Harrison & Bates (1991) cite reports that this subspecies is clearly flourishing further south in the Judean Hills (Ilani 1988) and that it occurs in the West Bank (Ilani 1986) although Ilani (1990) believes the subspecies of the Judean Desert to be *P. p. nimr*.

**Panthera pardus saxicolor**

The type locality for this subspecies is Asterabad in southern Iran where it was described in 1927. Its range is considered to extend east to Afghanistan and Turkmenistan (Nowell & Jackson 1996) and west to Turkey (Borner 1977). There is little evidence of this subspecies in the Arabian Peninsula region, the most southern records coming from a low lying area at Rawa on the Euphrates and yet further south on the floodplain of the Tigris at Kut al Imara in Iraq (Harrison 1968).

**Panthera pardus nimr**

As Harrison (1968) accounts, Hemrich and Ehrenberg’s (1833) *Felis nimr* was based principally on an Arabian skin from the ‘mountains in the vicinity of Qunfida, Asir, Saudi Arabia’ and Pocock (1932), nearly 100 years later, proposed that this form might occur on both sides of the Red Sea. However, Harrison, who had access to additional information, did not agree and considered the S. Arabian leopard, *Panthera pardus nimr*, as distinct and that any extension across the Red Sea was doubtful.

**Kingdom of Saudi Arabia**

Harrison (1968) reports specimens only from the Asir mountains (where the type specimen was obtained) that run southeast towards Yemen. He considered specimens from the Hijaz (to the north-west) to be *P. p. jarvisi*. However, later Harrison & Bates (1991) referred to just one subspecies, *P. p. nimr*, for the leopards of the Hijaz and the Asir.

In 1982 a live-leopard was seen in Wadi Hiswa in the Asir (Gasperetti et al. 1985), while Nader (1989) reported on killings of leopards and the collection of leopard remains in the 1970s and 1980s and concluded that if they remain in the Kingdom they would be in the Asir mountains. One year later Biquand (1990) reported on a survey of the Asir concluding that they were probably present although they made no sightings. In a subsequent paper Nader (1996) reported a small population still in the Hijaz and one also in the Asir, although no evidence was presented. Judas et al. (2006) report just four confirmed records since 1999 although three were based on evidence of tracks and livestock killing and only in the fourth case, near the Yemen border, were remains of two leopards photographed in 1999. A recent paper by Al-Johany (2007) based on a survey from 1998 to 2001 concluded that the number of leopards in Saudi Arabia was greater than widely believed and included 65 sightings by local informants. However, none of the records or sightings was substantiated by photographic or other evidence and since that time field surveys and camera trapping programs have failed to confirm the continuing presence of leopards.

A number of leopards were captured in the wild between 1997 and 2003 and subsequently acquired by the National Wildlife Research Centre (NWRC), Taif and other private collections. However, Judas et al. (2006) suggest that all, with the possible exception of a young male in 1997, were captured in Yemen.

In conclusion, irrefutable evidence that leopards still occur in the Kingdom is lacking. The last substantiated record appears to have been the two animals found dead in 1999 near the Yemen border.

**Republic of Yemen**

Sanborn & Hoogstraal (1953) reported that the species was scarce but widespread while Harrison (1968) reports several specimens of leopard from the mountains around Aden and Beihan. Obadi (1993) reports the killing of leopard during the late 1970s and early 1980s in the area of Lodar northeast of Aden.

Al Jumaily et al. (2006) provide details of post-1990 records for five broad clusters from areas in the north close to the Saudi border to the south in the Mahra Governorate and close to the Oman border. However, most capture records are from the area of Al Wada’a about 120 km north of the capital where Lagrot & Lagrot (1999) also reported signs of leopard as well as captures. A
spate of live-captures seems to have commenced in the early 1990s when a young female was killed in a leopard trap and her male offspring taken into captivity in Sana’a from where it was sold to the Breeding Centre for Endangered Arabian Wildlife, Sharjah in 1995 (Jongbloed 2001). In subsequent years at least 10 wild caught leopards entered zoos in Sana’a or Ta’iz (Budd 2003) and at least nine were reported to have come from the Al Wada’a area (EPAA 2000). Further animals were moved to the Breeding Centre for Endangered Arabian Wildlife, Sharjah and in 2002 an animal was wild caught and presumably sold to the Al Wathba Cheetah Breeding Centre, Abu Dhabi (Budd 2003).

**Sultanate of Oman**

In the Dhofar Mountains of southern Oman, leopards were known from the monsoon woodlands of Jabal Qara (Thomas 1932) and a specimen was collected from Jabal Samhan (Harrison 1968). It was from Jabal Samhan that leopards were captured in 1985 to establish the first captive breeding group (Usher Smith 1985). In northern Oman a single skin was obtained from the Al Hajar range (Harrison 1968) where in 1976 what is believed to be the last leopard was found killed. Specimens were recovered from the Musandam peninsula during a spate of killing in the early 1980s and the last confirmed report is of two animals killed in 1997 (Spalton et al. 2006b).

Camera-trap studies have confirmed the continuing presence of leopard in Jabal Samhan, Dhofar (Spalton & Willis 1999) where over 200 photographs of 17 leopards were obtained during the years 1997-2000 (Spalton et al. 2006a). Ongoing camera-trapping has also confirmed the presence of 9-11 leopards in Jabals Qara and Qamar that run west from Samhan to the Oman-Yemen border. A number of these leopards were fitted with GPS satellite collars and tracked in 2001-2005 (Spalton et al. 2006b).

**United Arab Emirates**

Harrison (1971) reports the presence of leopard from the mountains of the northern Emirates that border Musandam in Oman. In 1986 at least one leopard was killed in the same mountains and in 1991 a male was caught alive near Masafi while in 1992 one was shot in Wadi Bih (Jongbloed 2001). The male from Masafi joined the collection at the Breeding Centre for Endangered Arabian Wildlife, Sharjah but has not participated in the breeding programme. A survey in 1995 found tracks of leopards at one site and stated that there may be 20 ‘or far less’ adults in the mountains (Stuart & Stuart 1995).

A survey in the Emirate of Ras al-Khaimah in 1999 and 2000 found some signs of leopard but were not confirmed by camera-traps deployed at the same time (Llewellyn-Smith 2002). There is a report of a leopard being killed on the UAE side of the Musandam Peninsula in February 2001 (EPAA 2003) but photographs or carcass remains seem to be unavailable.

Figure 1 shows the confirmed, possible, probable and historical range of *P. p. nimr*.

**Morphological and Molecular Genetic Variation**

Miththapala et al. (1996), using molecular genetic analysis, grouped seven putative central Asian subspecies including *P. p. nimr*, *P. p. jarvisi*, *P. p. tulliana* and *P. p. saxicolor* together as the revised subspecies *P. p. saxicolor*. However, their analysis included material from only two of the seven subspecies: *P. p. sindica* (Baluchistan leopard) and *P. p. saxicolor* and the latter were represented entirely by a zoo-bred population.

This assessment was revisited by Uphyrkina et al. (2001) who used new genetic methods and additional samples. They had no material from *P. p. jarvisi* or *P. p. tulliana* and had one sample for *P. p. nimr* and three new samples for *P. p. saxicolor* that had not been used by Miththapala et al. (1996). Their work confirmed the proposed subspecies of *P. p. saxicolor* but tentatively considered *P. p. nimr* as a subspecies writing that ‘populations of *P. p. nimr* appear to have been isolated for quite a long time, accumulating multiple diagnostic sites that distinguish it from any other subspecies’. The single sample of *P. p. nimr* was obtained from Tel Aviv University but originated from somewhere in south Arabia.

A study conducted at the Breeding Centre for Endangered Wildlife, Sharjah (J. Williamson, pers. comm.) looked at possible differences between leopard from northern Arabia (UAE & northern...
this difference was significant for saxicolor and nimr ($P = 0.004$, df = 17). Body length of nimr did not vary significantly between those of the Judean desert, Saudi Arabia and Oman.

**Discussion**

It seems that once three subspecies of leopard occurred in the region. *P. p. nimr* is the principal leopard of the region and of the Arabian Peninsula in particular. *P. p. saxicolor* is a species of central Asia whose range extended south to southern Iraq and Jordan. *P. p. tulliana* is the only surviving subspecies of the region. However, for the other subspecies genetic studies have not come close to resolving the subspecies debate. The proposal by Miththapala (1996) to lump the other species of the region has little scientific base since it did not include any material from populations of *P. p. nimr*, *P. p. jarvisi* or *P. p. tulliana*. Similarly Uphyrkina *et al.*’s (2001) tentative suggestion of nimr as a subspecies has little credibility as it was based on a single sample.

Further genetic studies may help resolve subspecies issues. However, while we await such studies we should consider the likely reality that *P. p. nimr* is the only surviving subspecies in the region and that it does not occur elsewhere. In the Negev Highlands and Judean Desert numbers are very small and in the Arabian Peninsula it is restricted to Yemen and Oman. In Yemen leopards face severe persecution in the wild and in the last 10 years many have entered captive collections in the country and elsewhere in the region. However, there

* sub-adult; # tail damaged; OACE: Office of the Adviser for Conservation of the Environment, Oman
still remains an opportunity for in situ conservation. In Oman the situation is more encouraging with ongoing conservation programmes but the total number in the wild is likely to be less than 200.

Whatever further evidence emerges as to the distribution and subspecies status of the leopard in the region the reality is that the Arabian leopard or ‘nimr’ in Arabic has largely gone from the region and if it is to survive in the wild it will most likely be in the mountains of southern Arabia, and in particular in the Dhofar Mountains of Oman.
